

Restoring trust in human evidence in the age of deepfakes

At a time when deepfakes are blurring the lines between reality and fake, and identity systems are reaching their limits, digital security demands a break: restoring the reliability of evidence, and trust in human control.

Veintree offers a unique approach, linking the physical world to the digital realm to produce, in a single action, proof of authentication that is impossible to copy, impossible to store, and impossible to forge. It's a sovereign response to a challenge that has become global: guaranteeing the origin, integrity, and legitimacy of any action or creation in a world saturated with counterfeits.

\$410 million lost in just six months due to deepfake fraud: four times more incidents in the first six months of 2025 than in the whole of 2024⁽¹⁾

20% of global biometric fraud are already based on deepfakes capable of mimicking a face or movement ⁽²⁾

60% of losses now affect individuals, who have become the primary targets of attacks that present themselves under the guise of someone else ⁽¹⁾

These figures reveal a shift.

The ability to generate and manipulate images, voices, and videos profoundly transforms the way identity circulates, presents itself, and is usurped. For the first time, it is not simply data that is stolen, but an appearance, an identity, and even the ability to act in lieu of a real person.

The problem is not limited to deepfakes. They are merely the visible top of a much deeper iceberg : our

digital identity verification models are reaching their limits. The mechanisms meant to authenticate are, in practice, reduced to recognizing a pattern, not confirming the presence or action of a real person.

Deepfakes, identity, and trust: why proof of the presence or action of a real person is becoming the global issue

For the first time in history, images, voices, faces - and even identities - can be artificially generated on a large scale.

If the digital authenticity crisis is so profound, it is because it strikes at the very heart of our current identification systems. Two main categories coexist, and both are vulnerable:

“External” elements: passwords, codes, cards, belonging to the world of Web 2 but also private keys, tokens, wallets of web 3 can be stolen, copied, intercepted, or stored without the users’ knowledge.

“Internal” elements – traditional biometrics – such as fingerprints, face, iris, voice, and gait, seem more secure because they are bodily. However, they can be captured remotely, cloned, synthesized, falsified, and require comparison with centralized databases, a major vulnerability.

These methods also involve the continuous transmission of personal information, such as identity details, images, and physical characteristics, which may be considered confidential and which one may not wish to expose. These sensitive elements, once compromised, can never be revoked.

**Deepfakes do not bypass our systems,
They exploit their very foundations**

Whether they originate from outside or within, identification mechanisms share the same flaw: they can be copied, stored, or presented, used by someone else. And because they rely on pattern recognition, these identifiers cannot authenticate, that is, prove the person's actual presence or action.

What can be copied can be stolen. What can be stolen cannot be trusted.

To overcome these limitations, it is not enough to improve existing systems: the logic must change: identity can no longer be based on a stored code, object or model but on proof of authentication generated only when the person is actually present.

This is the breakthrough offered by Veintree, a French start-up that is developing a new unique post-biometric authentication solution, based on the recognition of a living, non-stored, uncopyable and confidentiality-preserving proof.

This approach, which redefines the standards of authentication and digital trust, is now receiving international recognition: Veintree has been selected as an Honoree of the CES Innovation Awards® 2026 in the official Filmmaking & Distribution category, in partnership with Cannes Next ®

"Your hands. Your key. No database. No trace."

Veintree uses a unique biological characteristic, a living signal impossible to copy or lose: the network and venous flow of the hand, to create, with each use, an anonymous proof of authentication, without production or storage of biometric data.

"There is another way, one that doesn't rely on exploiting the human body, but on proving human presence without revealing identity. This approach, which we call Human Proof, makes it possible to demonstrate that an action, a decision, or content was produced by a real human being, physically present, without ever storing their biological data." Christophe Bron, Board President, Veintree

Instead of storing who you are somewhere, Veintree provides unique proof of human existence: the guarantee that the person authenticating is indeed the legitimate person, without ever retaining or exposing their identity.

The venous flow in the hand is at the heart of the Veintree system: It allows in the AuthEnTHICator's permanent memory to generate a **digital lock** intrinsically linked to the individual. The key to this lock relies exclusively on the living, unique, and dynamic signal generated by the presentation of one or both hands. Invisible to the naked eye, this signal is far more complex than a PIN code or a biometric image and cannot be artificially copied or reproduced.

This analysis is performed by the AuthEnTHICator, Veintree's authentication device, designed to transform this live proof into biocryptographic proof, without ever storing biometric data.

Venous networks constitute one of the most reliable biological signals:

- invisible to the naked eye, internal, contactless and impossible to detect remotely.
- Inimitable: impossible to reproduce or counterfeit. Approximately 10
- times More secure than iris scanning, approximately 100 times more secure than fingerprints, and approximately 1,000 times more secure than facial recognition *
- Stable over time

Biocryptography is a discipline that uses a

living biological signal to produce cryptographic proof — that is, mathematical information that can be used to secure, sign, or authenticate an action — without ever storing the biological signal itself.

➡ In practical terms, when the hand passes in front of the sensor, Veintree never records it.

The hand acts like a living key, activating the AuthEnTHICator. The sensor analyzes the dynamic vein signal in real time, then instantly transforms it into **ephemeral mathematical formulas**. These formulas generate a **unique key**, complementary to an encrypted formula, "the lock," securely stored in the sensor's memory.

Each time it's used, the same action generates a new ephemeral key, as well as a digital cryptographic proof token. This token can be transmitted either to a blockchain or to the server responsible for recognizing the user, depending on the use case.

This inseparable duo, "living lock + ephemeral key", makes it possible to authenticate a person without ever capturing, storing or knowing their identity.

Veintree does not say who the person is, it proves that the person is real, present and legitimate to perform the action.

This is a new way to protect creation as well as the creator, to secure productions and to restore a link of trust between the one who publishes and the one who reads, watches or shares.

The authEnTHICator will be available for pre-order in the second quarter of 2026 on the Veintree website: veintree.eu

Patented technology.

- 0 false positives out of 42 million tests

Native GDPR compliance

- Post-quantum resistance: use of algorithms conforming to NIST standards (LWE family – Learning With Errors).
- Dynamic 5-factor authentication in a single step
- Proof of ignorance ("zero-knowledge like"): authenticate without revealing identity.

A technological foundation for a wide range of sovereign applications

This ability to produce live, instant and unstored proof opens up a very wide range of applications: **access control, signatures of actions, certification of transactions, protection of digital assets or even guarantee of integrity for sensitive interactions.**

It is in the field of content creation, a decisive issue in the era of deepfakes, piracy and copyright violations, that Veintree is deploying **its first concrete user case: the authentication of creation, whether digital, written, audiovisual or cinematographic.**

Authenticate and protect the creation at the source

What Veintree guarantees for a person, it also guarantees for content.

Authentication by hand becomes the signature of the content: it allows us to attest, at the very moment of creation: text, image, video, avatar, **that an authenticated human is indeed the author and that any modification or misappropriation would be immediately detectable.**

This signature instantly provides what is currently lacking in digital content:

- the certainty that the content was indeed created or validated by an "authenticated" human, a declared "human authority".
- protection of creative works, by making any attempt at usurpation, modification, hacking, or misleading attribution immediately detectable,
- a signature designed to resist fraud and ensure traceability of content.

At the time of creation, the creator passes its hand in front of the Veintree sensor. This gesture generates an authentication token, and a copy of it is instantly embedded as an **invisible watermark in the content (texts, photos, videos, films): proof of anonymous origin specific to that content.** When a journalist, newsroom, or platform receives this content, they can verify, in a few seconds, that the accompanying watermark is identical to the authentication token;

- If "yes" the content is certified authentic, never modified;
- If "no" the content has been altered, corrupted, deepfake, and thus to confirm the source and integrity of this content

A closer look at the media use case - wazup-intech.com, the first pilot media project

Wazup-Intech is the first media outlet to experiment with Veintree technology to sign and certify the authenticity and human origin of its editorial content, including its video news presented by avatars and augmented by AI.

Wazup-Intech's video journals, reports and video press releases are based on real journalistic writing, while being embodied on screen by avatars.

This approach, designed to make technological information more accessible, raises a question that has become central: **how to prove that content presented by avatars or new AI technologies is indeed the result of human work, and not artificial generation?**

**Veintree provides a concrete answer to this challenge:
authentication of creation at the source.**

Every piece of content published by Wazup-intech is signed upon creation, guaranteeing that the information:

- stems from human journalistic work, even when presented by an avatar,
- was not generated, manipulated or counterfeited by AI or a third party,
- remains protected against any modification or usurpation,
- can be verified in one step by any newsroom or platform.

This user case opens a new path for the media: **making the human origin of content visible and verifiable, and helping to restore trust in the age of avatars, deepfakes and automated production.**

Founded by Dr. Christophe Bron, Veintree was born from field experience before becoming a technological project. A doctor by training, involved for several years in humanitarian operations in crisis zones, Christophe Bron was confronted with a brutal reality: **the impossibility of proving the existence and legitimacy of people when all administrative identity does not exist or has disappeared.**

In Haiti, after the 2010 earthquake, the lack of civil registration and reliable systems made it impossible to identify victims, including children separated from their families. From this experience emerged a fundamental insight: **proof cannot always rely on identity, but must also rely on human presence itself.**

Veintree was born from this observation. Its ambition: to **restore reliable human evidence** in contexts where appearance, documents or data are no longer sufficient, and to **extend this ethical requirement into the contemporary digital world, marked by the massive falsification of content and identities.**
